Each team was given a Sparkfun OpenLog in class on September 12th, 2017. These will be used for this homework as well as upcoming in-class exercises. It is expected that everyone on the team meaningfully participate with this homework. Each team shall bring hardware from HW #04, plus hardware built below, to class on September 19th. ALL STEPS SHALL BE COMPLETED BEFORE CLASS TO RECEIVE CREDIT FOR THIS ASSIGNMENT.

1. Find the hookup guide for the OpenLog (shown below) on the Sparkfun website. Understand how to connect the OpenLog to your Arduino and how the Arduino uses serial communication.

2. Find the data sheet for the 3 axis accelerometer on the Sparkfun website. Save a copy to your laptop. Find out how to convert from voltage to Gs by using the data sheet and show method/equation below. Also understand and determine the settings needed to configure this sensor for your balloon flight.
3. Find the data sheet for the humidity sensor on the Sparkfun website. Save a copy to your laptop. Find out how to convert from voltage to RH using the data sheet and show method/equation below. Also understand and determine the settings needed to configure this sensor for your balloon flight.

4. Solder the two 330 ohm resistors to the Balloon Shield as shown. Solder from back side of board and trim leads.
5. Solder 2 two pin headers to the D4 and D3 location on your Balloon Shield. Short pins go into the board and are soldered from bottom of the board. Long pins should be on top. This is very important.

6. Solder one 3 pin header connector to the HUM location, two 4 pin header connectors to the PRES location, and one 6 pin header connector to the ACCEL location on your Balloon Shield as shown. Header connectors must be perpendicular and flush with to the Shield board. Solder connections are made on the bottom of the board.
7. Solder one 3 pin **locking** header connector to the TEMP2 location on your Balloon Shield. Short pins go into board and are soldered from bottom of board. This is very important. **You MUST install the header exactly as it is shown in the picture.** The locking mechanism can only be inserted one way and installing the connector backwards will result in the temp sensor overheating and destroying the space-time continuum.
8. Solder one 6 pin header connector to the OPENLOG location. Solder connections are made on the bottom of the board.

9. Your final product should look like the picture below.

10. What is an analog sensor?
11. Identify the analog plot and the digital plot.

12. What does ADC stand for?

13. What does an ADC do?

14. Does the Arduino Uno have one and if so what resolution is it (4 bit, 8 bit, 10 bit, 16 bit, etc)?

15. How many states are in a 2 bit digital conversion?

16. How many states are in a 8 bit digital conversion?

17. How many states are in a 10 bit digital conversion?

18. How do you convert a 10 bit digital value back to an analog value if the analog range is 0 to 5 V?

19. Using your method in question 18, complete the following conversions in the graphic below:
